## 1. Biodiversity loss and financial risk

November 10, 2010

### Opening Statement - Alejandro Glez de Caceres, Governor, Banco de México

Mexico is a biologically megadiverse country. It occupies the fourth place in the group of six megadiverse countries having more than 10% of the globally known species. Unfortunately, it is threatened by climate change and deforestation originating agriculture and livestock economy, as well as by air, water and soil pollution, unsustainable fisheries, and the pressure of unregulated and unplanned urbanization. These problems are particularly acute, not only in Mexico, but in most developing markets and megadiverse countries.

The issue of biodiversity loss is intrinsically linked with market failures and the difficulty to internalize and properly value and price the externalities caused by activities that erode biodiversity and natural capital.

This pressure can place an asymptote to the sustainability of economic activity, as it impairs the health and living conditions of both current and future generations, eroding national economic and financial risks (threatening and reducing natural capital is essential to mitigate these risks).

Regarding natural capital loss, despite the global externalities, the financial community is not beginning to understand the value of ecosystem goods and services for economic activity and sustainability. There is a strong link between climate change and biodiversity loss. When considering their specific externalities in the transition to a sustainable economy, it is essential to take into account climate change and biodiversity loss together. Using biodiversity and natural capital values (developing and valuing ecosystem power and flow markets).

There is a growing recognition among international businesses and the financial community that nature must be explicitly considered as part of the economic analysis and cannot be processed separately as a separate system.

As human activities continue impacting nature and the economy, we will face increasing physical and transition risks.

Nonetheless, there are many tools that companies and market participants can use to assess the impact of ecosystem services in critical economic sectors, such as agriculture, forestry, construction, electricity generation and construction materials, among many others. The conference will address how some of these tools and frameworks provide relevant information to the market participants on nature-related financially material risks.

As financial institutions continue to share the benefits of ecosystem services and the potential for nature-based solutions, they will promote and improve their own green and social identity, potential investment opportunities, and bring together financial flows activities.

However financial institutions are beginning to be used for ecosystem conservation. With the support from the private, financial, and other institutions, financial institutions can play a crucial role in addressing the risk and opportunities associated with restoring and conserving biodiversity and natural capital. This can be achieved by promoting nature, standards, disclosure practices, and integrating biodiversity-related risk factors into financial decision-making.

By ensuring that financial institutions have access to information on ecosystem services and dependencies, promoting nature-related financial disclosures and integrating natural information into their financial business, authorities can contribute to the preservation of natural capital. Financial authorities can also consider the role that credit business can play in collecting and providing data to credit institutions on the environmental compliance of borrowers. By sharing this information accessible in their reports, credit business could build strong proximity between its firms that supports the commitment, especially in emerging markets with a small rate of loss.

Finally, central banks have been given authority to ensure that their short-term political pressures, giving them the flexibility to pursue long-term objectives through the principal function of central banks is the provision of money. Subsequently financial policy can tend to also tend under the long-term perspective, that actions tend to be aligned with broadly defined social welfare and sustainability objectives, which are precisely the issues that will be addressed at the conference.

## Opening statement : José Sanz-Sánchez, coordinator of the National Commission for the Knowledge and Use of Biodiversity (CONABIO)

What are we going to achieve by focusing on local solutions within the landscape boundaries?

Managing the space has examples of the kind of elements that are needed to make successful and robust interventions for the conservation of biodiversity, not only for the sake of nature itself and the ecosystem but also for the people who live and depend on those ecosystems for their well-being and livelihood. Very precise and detailed information on the biodiversity is needed, everything from species to ecosystems and depending on the approach, also on the groups of plants, like for example all the edible plants on which we depend. There is a need to develop analytical platforms that could help effective decision-making on where to develop projects, where are the best places, how to manage them, and how to ensure that the interventions are achieving the sustainability goals set from the beginning. These decisions must be based on the best possible science and information, otherwise it's a sort of shooting in the dark. Additionally, in addition to such a better planning instrument, it is necessary to include in the decision-making the people who live in these landscapes, already indigenous peoples, and local communities.

To make good decisions on decisions on where to invest and implement biodiversity conservation projects, it is necessary to know beforehand which areas are a priority for conservation or restoration strategies. There is information a strategic consultancy platform that guide where to invest money in restoration, conservation and sustainable management of land and water ecosystems. We have worked both the knowledge and the old governments to generate a common map of areas without changes which is comparable with foreign common maps. It can be used as a first step to detect how healthy an ecosystem is, what there with enough technical knowledge of the biodiversity ecosystem, species, a relative factors.

CONABIO has a map that shows the integrity of the ecosystem, measuring the completeness of the structure of plants and the whole platform of different animal groups of the ecosystem. The closer to an area healthy ecosystem, there are the better they are, the healthier they are, the less have changes caused by man but with natural components, there are an ecosystem. The information is also extremely useful for decision-making on where to invest to preserve ecosystem. The map also identifies the best areas where protect species with a high-risk of extinction, also in a combination of human impacts and areas that have to do with climate change and their impact on the species and ecosystems.

What work has been done for coastal ecosystems as well where monitoring is done every five years on the changes in ecosystem structure as well as the use and cover. With the technology we can know how much impact and who the impact of these areas.

INSTITUT has also developed a platform that helps preserve forests and ensure that the agriculture sector does not keep expanding, degrading natural and coastal ecosystems. This platform was implemented a few years ago and has generated the approval of agricultural activities in areas that need protection. We are the first country with that type of technology.

In conclusion, if this conference is taking place in a virtual form, it is precisely because we have already identified and focused on many components throughout the globe that the pandemic that we are suffering now has forced us to move virtually. From the middle ages or even before, pandemics have originated from components deterioration and causes deterioration of such components. It will keep happening as long as the conditions are not healthy. The loss of biodiversity in a country just followed a loss of healthcare, not only ecological but also economic, political, and social.

We have lost and may lose' housing, ethics, sciences, health sciences or manufacturing sciences on the loss of biodiversity loss and the importance of preserving healthy components to have healthy ecosystems and economies that are durable and sustainable. This is something that needs to change.

## **Keynote speaker Henry M. Pacheco Jr., President, Pacheco Institute, Latin America Conservation Council (LACC)**

What has led to the biodiversity loss crisis? There are many causes, from population growth to climate change.

The approach of the conference is on the political and economic market systems that have created biodiversity as nonmarketable, so if we acknowledge they have failed to recognize the value of natural capital and to account for the value of natural capital in our market-based systems.

It's not as difficult to give a greater value to natural capital. If we do not set a value, natural capital gets treated as essentially being free, and politicians put less value on it. The result is adopt our market-based systems so that the markets, citizens, and policies are oriented to account for and preserve natural capital and protect those that destroy it.

This is difficult, when we talk about changing policies and practices and economic models, because politicians have a strong incentive to keep their jobs, which makes it very difficult to make short-term gain for long-term prosperity. Nevertheless, we know that we must better to preserve natural capital than to deal with the costs that make up for the correction and the consequences of what was destroyed.

Scientific research makes it much easier to understand the biodiversity loss, changing policies and in many ways, even more so during these climate change. Regarding climate change, there is a lot of scientific research done, and we have the scientific studies and forecasts. However, with biodiversity loss, there is not enough work to know what the real consequences will be for our ecosystems. A study by the Chinese government showed that you could do things that don't cost a lot and make a big difference. Most of the political action from an economic model that needs to be updated.

There were no change food production, in ways that didn't destroy biodiversity there would be supplementary resources of about one billion dollars a year. What we need to do is redesign the system so that it properly accounts for nature. That will save not only nature, it will save their property.

The role of financial institutions in solving the problem is tremendous, but not without financial support without government support.

Financial institutions should be transparent and open regarding not modeling sustainability, how, and where and standards for the disclosure of loans or investments that harm natural capital is required. There is a need for standards for transparency, verification, and accountability. In addition, the government through the financial institutions the tools in terms of the proper regulation, and incentives to avoid the destruction of natural capital. What is happen today with biodiversity conservation is that we are getting many facilities that using the tool, but we have to keep fighting.

Regardless whether people and local communities, it is important to think about preserving culture without coming up with a way to make this work for them. You can't have people living in urban poverty and expect them to look after preserving watersheds.

## Panel 1: Assessing biodiversity risks on the financial system

What are the key characteristics of biodiversity-related financial risks? What are the similarities and differences between the climate and climate-related risks? Why should financial institutions integrate biodiversity risks in their financial decision making? How are central banks and financial regulators reacting to these risks?

**Moderator:** Lucinda Maclean, Secretary, Board of the International and Local Bank Association, a global bank group, Toronto, Canada

**Setting the stage:** Robert Watson, Professor, University of Environmental Science, Technology, and Society

### Panel participants:

- 1. Hans Hoekstra, Director, Division 4, Senior Counsel, Division of Ecology/Environmental Sciences, University of Minnesota
- 2. Neil Wilson, Professor of Practice, Sustainable Finance, Executive Research Institute, The Center for Global Economic and Political Science (CGEPS)
- 3. Wang, Thomas F, Co-Editor, *Journal of Banking and Finance*
- 4. Robert Maclean, President, Bank of Montreal
- 5. William Waring, Head of Implementation, the International Sustainable Finance Centre

### Panel 1: Assessing biodiversity risks on the financial system

The panel discussed different aspects of financial risks stemming from biodiversity, in the context of an increasing demand for integrated nature. There is a representation of nature capital as well as other environmental issues that provide supply of a higher nature value. Some insights of the panel were the following:

• The economic and social impact of the decline in ecosystem services can be estimated if the value of nature is incorporated into national accounts consistently, and with a proper institutional framework, cooperation of stakeholders

There is a growing interest from financial institutions and central banks regarding the dependency on ecosystems

Climate change features a starting point to assess biodiversity, as the two are interconnected and affect the financial system. The current level of biodiversity risk is, therefore, at least moderate, rather than being given by low likelihood and resulting complexity

## Robert Watson, Professor Emeritus, Tyndall Center for Climate Change Research, and University of East Anglia

Nature provides essential services essential for human existence and well-being, companies are highly dependent on them, and have a huge footprint on biodiversity and our future is generally in the hands of nature. In a recent paper called “Nature not money”<sup>1</sup>, we presented a view that there is a risk that the focus is slipping to an unbalanced view. We are seeing changes in the land use, the loss of forests, grasslands, mountains, nonurbanization of our farms, and animals, weakening climate change, changes in temperatures, precipitation, sea level, ocean acidification, pollution caused by the excessive use of agricultural chemicals, fertilizers, pesticides and herbicides and species, these direct causes often leading to loss without the natural cause, threatening the growing demand for food, energy, water, and other resources, due to rapid economic growth all over the world, population growth, international trade, and technology.

Unless we meet the Paris climate goal of reducing global warming to a significantly lower increase of one degree below by 2100 (probably only 1.5 degrees below) climate change is likely to become the leading cause of biodiversity and ecosystem services loss.

Wildlife conservation services continue to increase, natural food production, most regulatory services are declining significantly.

We need to recognize that climate change, biodiversity loss and nature degradation are no longer just environmental issues, they are also economic, development, security, moral and ethical issues. Climate change is impossible to meet the environmental development goals of the richest nations, and moreover, while industrialized countries are making responsible for most of the environmental degradation, the most vulnerable are poor countries and people.

In strategic documents around the world, not all the goals trying to ensure alignment thereby. By 2015, some were fully met, and some most steps towards the most hope that when shaping the 2030 Sustainable Development Framework the objectives and goals will be accompanied by measurable actions.

We have a great deal to lose that we are also failing. Unfortunately, all the current positions that most countries of the world support that resources in 2015 will be the the maximum. Meaning in mind that climate change and biodiversity loss are interconnected as environmental objectives and actions between the two conventions (Convention on Biological Diversity and United Nations Framework Convention on Climate Change).

---

<sup>1</sup> Nature not money, 2016, the first report of Nature Matters for Business with the University of East Anglia, Tyndall Center.

<http://www.tyndall.ac.uk/reports/nature-not-money-2016>, the accompanying nature matters for business and the 100 policy.

One of the important uses of sustainability is in the fact of recognition that nature is finite and the built economy and social system institutionalized, rational, and efficient. To achieve a sustainable world we need to redefine our relationship with nature, as well as the economy, the state, and production system. We need to use nature capital as human capital as part of national wealth, along with built human capital. The use must further measure of sustainable economic development that that gives economic growth, which of course increases economic growth, but not sustainable economic growth. Sustainability needs to be achieved and therefore the price of environmental degradation needs to be internalized in the price of goods and services, independent of what is produced.

There is a need to adopt a circular economy sustainable production, and consumption, and recognize the interrelationship between the agriculture, the energy and the water sectors. It is also clear that these issues are not only the responsibility of governments, but need to include the private, a civil society sector, international organizations, NGOs, religious groups and local communities, the society at general, the media and the academia. However, governments must lead by changing their attitudes thinking and support accordingly. Finally, the financial sector, banks, private equity, and insurance companies have a very important role to play with their stakeholders.

Nature contributes greatly to public goods, produces many public goods with associated costs, and activities are not internalized. There is a lack of incentives to continue supplying the kinds of public goods that nature capital generates. However, the current market system, price mechanism, and the private sector are ill-equipped to supply and maintain natural capital. Thus, public policy has a role to play.

This is an important message: we need to transform our economic and financial system to incorporate the value of nature so that it counts as much as anything counted in the economy and human well-being.

One last point: that where we are financially rich and where we are rich in biodiversity are not the same parts of the world. Thus, we need to pay attention to how we coordinate international financial flows so that we can protect nature.

## **Wiel Hahnel, Professor, Institute of Research in Economics, London School of Economics and Political Science.**

the structure of central banks and supervisors for steering the financial system (FSMT)<sup>1</sup>, comprised of the financial system with hundreds of central banks and supervisors, along with the international network for sustainable financing (including information, research, and exchange) (FSMTIF) and the global governance group (a high quality group) such as what the International Monetary Fund (IMF) has with its members? What does the need for the structure of central banks and supervisors? If needed, what does the need in the context of financial risk?

Nonetheless, the world's financial and investment system is a financial risk. This happens in spite of the fact that financial institutions and central banks are beginning to understand many financial institutions ultimately rely on healthy economies.

Financial institutions may be inclined to looking at investment activities that have negative impacts on sustainability. Therefore, governments implement appropriate policies and central and market regulators change financial institutions may face transition risks due to changing corporate objectives. At the same time, the financial institutions change strategies about sustainability and there is the opportunity for an integrated approach in managing climate and sustainability related risks.

Financial central banks are beginning to assess these risks. How often these risks do we assess that sustainability risks are properly incorporated into mechanisms for developing financial markets? There are also central banks that begin to apply sustainability criteria to the management of their own portfolios (the main central banks and the banks of finance).

There are things that can be done, such as ensuring that financial flows are aligned with sustainability values, very similar to the financial provisions of the Paris Agreement. The need to ensure that the impact and dependence of business and financial institutions are properly assessed and reported through financial markets such as better sustainability disclosure aligned more closely with the construction and preservation of nature.

Looking back on the 2015 G20 meeting, it is clear that without adequate attention to nature, the climate objectives of business and finance will not be met. We must build upon the financial institutions that have joined the Glasgow Financial Alliance for Net Zero (GFANZ)<sup>2</sup>, and have committed to net-zero portfolios by 2050. The real challenge is how to transition into actions that reduce the negative impacts of biodiversity loss.

One of the most pressing issues is that emerging economies are more dependent on healthy ecosystems and will be more affected by the collapse of biodiversity, but they have contributed the poorest financial flows. That is a challenge. How does it increase international financial flows, both in terms of public and private flows, to restore and sustain biodiversity?

<sup>1</sup> Group of 20 Leaders' (2015) Letter to the G20 Leaders. <http://www.g20.org/letter>

<sup>2</sup> Glasgow Financial Alliance for Net Zero (GFANZ) Glasgow Financial Alliance for Net Zero. <http://www.gfanz.net/>

## **Thulaja Thomas K Viswanathan, Executive, Central Bank of Malaysia**

Why should financial institutions consider the role of biodiversity loss? If the financial sector is trying to address the role of climate change, it must also understand that the role of biodiversity loss is highly intertwined with it, and address the role of climate change.

In the next stages of strategies, biodiversity-related risks have begun to be analysed. We know that climate matters benefit from the momentum of the climate change agenda, and this has led to the development and advancement of tools and methodologies, and to the integration of scientific knowledge and financial sector analysis.

Malaysia is an emerging economy with great biodiversity and ecosystem richness, numerous activities and livelihoods. Understanding the dependencies and impacts on ecosystem services has become a must for the business and understand how to conduct an analysis of the financial sector. We are using tools to map dependencies and impacts of the entire financial sector giving visibility to ecosystem services.

The connection around biodiversity risks is intertwined with climate risks and how each component with each other, and how this relationship itself could evolve as it identifies priority areas within an emerging economy.

The loss of biodiversity can have very local-specific effects and consequences, so methodologies must be contextualised. This will make it possible to build relationships and connections with other local actors. We recognise that we need to work very closely with the government and many of the local parties, including civil society.

This exploratory approach involves engaging and having conversations with other stakeholders outside the financial sector. It must be understood that biodiversity-related risks are intertwined with social and health impacts and consider biodiversity and environmental policies as a very important part of the management agenda. Mostly, different types of methods need to be applied, including qualitative ones as there are data limitations that affect the ability to quantify.

## Remain Ecofiscus, Ecofiscus, Banque de France

If we want to have a comprehensive approach to risk management, it is good to analyse climate change, but we must also examine other potential impacts and risks that could arise, both physical and transitional, related to biodiversity loss.

With the creation of the TCFD, probably in the coming years, there will be more expectations for financial institutions to better understand financial risk related to biodiversity and its interaction with climate-related risks and more towards the demand to have a better rating with a scientific perspective.

In France, the Energy and Climate law adopted in 2017 expanded the legal requirements that already existed for financial institutions regarding climate change to biodiversity. It states that from 2020, financial institutions have to disclose their impact on biodiversity and their dependence on biodiversity and ecosystem services. In addition, they will need to explain how these impacts are connected to transition risk and how these dependencies are connected to physical risks. This law requires financial institutions to discuss how their strategies align with objectives of biodiversity conservation goals.

It is important to remember that, for climate and biodiversity, non-financial policies (for example, industrial) are needed too that be careful on how much financial institutions can do and how much we want them to do and what that about the undesirable consequences, for example, potential greenwashing or players scaling back or replacing others. The measure is not with the institutional concern is what the financial system is integrated with other institutions.

The risk-based approach linked to biodiversity does not have impacts on prices, or on financial stability. In Banque de France working paper of the Bank of France institutions the case for central banks, this was treated as a complex problem due to the lack of structural factors among other aspects. The results state the discussion about where to go and how to deal on monetary including the connection to the climate.

## **William Bentley, Chief of Implementation, IIS concerned Sustainable Insurance Forum**

The Sustainable Insurance Forum (SIF)<sup>1</sup> is a group of 18 insurance supervisors and regulators working to understand and strengthen responses to sustainability issues, initially the work focused on climate risk. Past work developments include clear that nature-related risk should be considered by both the insurance industry and supervisors.

The global insurance sector is beginning to take a more holistic view of nature-related risks to expand beyond climate and natural hazard risks. The 1st recently published study to explore and understand the dependencies of the insurance sectors on nature<sup>2</sup> the study employed a mixed research methodology using a survey of 100 insurance sector participants from 14 countries, including insurers, reinsurers, insurance brokers and industry associations.

Keyway points outlining the study regarding the industry's future are the impact of physical and transition risks. Physical risks result from the natural deterioration of nature, causing both direct and indirect financial losses for companies and insurance companies. Transition risks encompass those that arise due to global policy, regulatory, economic and market transformations.

Nature-related risks to economic sectors are concentrated in the broader economy at both the macro and micro levels, leading to increased financial risks for the insurance industry. There is a potential increase in insurance operations, liquidity, market, and credit risks.

As the loss of nature increases, there financial and economic risks could increase in magnitude and frequency. However, nature positive activities, whether insured or financing the insurance industry, contribute to the conservation and preservation of nature, and can have a positive feedback loop to reduce physical and transition risks.

The insurance sector understanding of nature-related risks and collection of relevant data and mapping of risks to assess those risks is at a relatively early stage. However, actors in the industry are already using despite the absence of explicit frameworks to incorporate nature-related risks into assessments and management practices.

Some actions highlighted in the report are the need for insurers to begin assessing risks and impacts to report and disclose their risks; manage their assets to positive practices and develop insurance products aligned with nature. To insurers and reinsurers, we have said that to continue to identify and create new capital flows, markets, and forward-looking indicators to assess and measure nature-related risks.

<sup>1</sup> Sustainable Insurance Forum (SIF) Board (2023 July 6) Sustainable Insurance Forum (SIF) <https://www.sustainableinsuranceforum.org/>

<sup>2</sup> International Association of Insurance Supervisors (2023, 2023) Supervisors' Report on Dependencies of Financial Institutions on Nature (SIF)

<https://www.sustainableinsuranceforum.org/wp-content/uploads/2023/07/Supervisors-Report-on-Dependencies-of-Financial-Institutions-on-Nature.pdf>

another point is to disaggregate the level of assets and liability-related risks by regions and sub-regions, and countries, as well as by types of risks. This can help to develop a diversified portfolio globally while sharing relevant strategy of risk management practices.

To measure exposure, we recommend identifying and rating business units required under reporting risk and encouraging the use of voluntary frameworks and international sustainability standards. At the end of the climate change process as a platform that provides resources for equity building in nature's risk and sustainability.

Regarding the methods, there is concern that there is no single universal framework that provides the most metrics to be tracked, which can be easily combined into a supervisory tool rating. It is thus recommended to start with qualitative work.

### **Keynote speaker Elizabeth Maruma Muroa, Executive Secretary, Convention on Biological Diversity**

One first message is that, beyond climate change, biodiversity is now recognized as a real challenge for the financial sector because it is connected to both the climate and biodiversity of our planet and for all of us. The conference of the Parties of the Convention on Biological Diversity and climate change has made it clear that it is important to include indigenous, local communities, and indigenous people in solutions. They have given direction and become a clear message that they must collaboratively with towards nature positive and nature-centric models.

The participation of all actors, in addition to governments, including business, the public and private financial sector, is an important challenging markets solution. There is a commitment to look at all aspects of the economy, including financial institutions, to contribute to reducing and building nature. There is an urgent need to consider nature beyond climate in all decision-making processes of the government and business and financial levels. Natural finance are more.

The role of nature is enormous, and the opportunities for action are just as significant because half of the world's GDP depends on nature. There are tremendous economic opportunities that are important for businesses and financial institutions.

Nature is the most critical significant change is a critical aspect, and nature was part of the climate discourse. The Glasgow first time recognized the importance of protecting, restoring and enhancing nature as a response to address global climate ambition. More than a hundred world leaders committed to ending and reversing deforestation by 2030, and the Glasgow financial leaders for the first time publicly was founded the new nature finance of the international sustainability standards board (ISSB). All these commitments must be followed by concrete actions on the ground of truly taking the difference we expect.

the central goals, targets, and therefore, the three shift the focus to what counts, why we failed and how best the means to its better treatments and measures for future, with respective leadership, management, local, strategic and political considerations. Successes of nature conservation can be a potent force to move forward and influence business strategy. At the same time, a robust disclosure framework will support the alignment of financial flows with positive results and with the three dimensions of biodiversity framework.

The key issue for Nature-related financial disclosure (NRFD) is a market-driven initiative for the market in collaboration with public development banks, other stakeholders and experts in the field of biodiversity. NRFD initiative provides a framework for shift for the new institutions and organizations, to report and act on the condition of nature-related risks, and to support a shift in global financial flows away from nature's adverse outcomes to positive outcomes.

It will build on the risk-based on climate financial disclosure (CFD) structure and foundation and will leverage synergies to avoid any potential conflict or duplication. Thus, these two frameworks will complement each other. Better information will enable financial institutions and companies to incorporate nature-related risks and opportunities into their business-making processes.

The term nature-related risk refers to the risks and opportunities for an organization posed by the links between its activities and nature. In addition to climate-related financial risks, they also include non-climate risks represented by the impacts and dependencies of nature. What does this mean? It means that organizations should not only how nature can positively or negatively impact the primary financial components of the organization from the outside in, but also how the organization positively and negatively impacts nature, therefore, from the inside out.

NRFD has different working groups for the definition of risk related to nature, impacts and opportunities for the consistency of data, standards, and metrics; to integrate a better understanding of the risks and opportunities associated with nature; and also for pilot developments. There is also a focus that form a global multidisciplinary consultation network of institutions that share the common mission of the NRFD that is to drive consistency and regulation of these on non-climate standards, metrics, and framework that enables adequate support consistency as a condition of regulatory compliance as guide for business making.

As movements have been made in favor of nature beyond nature, this is very encouraging for us, and they must now be followed by concrete actions on the ground. The introduction of non-climate and regulatory context.

## Panel 2: Disclosures, information, and tools

not possible and situations require flexibility: role in the existing tools & information can change things?

Robinson: to stage success, level of the climate change financial risk, information

Panel participants

- Kate Smith, Senior Program Development Manager, GreenAction
- Margaret Rutledge, Sustainability Practice Leader, North America Trust
- Richard Robinson, Managing Global Market Economist
- Richard Robinson, Director, National Business, Environment
- Richard Smith, Senior Lead, Environmental Issues, PFI

### Panel 2: Disclosures, information, and tools

this panel discussed information challenges in the financial system to incorporate biodiversity risks in financial decisions. Some takeaways were:

- It was thoroughly discussed the importance of considering jointly climate change and environmental degradation. The market to create and manage these risks together could drive a higher costs and a stronger financial link between them.
- Biodiversity also tends to have problems of availability, completeness, accuracy, consistency, and comparability. These problems hinder investments decisions due to the lack of uniformity of ecosystem reports.

## **Belanda (Gubernur, Gubernur, Gubernur, Gubernur)**

The central issue is how the current limitations of technology data availability are being addressed. The International Statistical Institute (ISI) will no longer show statistics and statistical institutions to be regarded as economic progress<sup>1</sup> in case it is the time to implement the ISI.

It is important to include not only costs and flows, but also the cost of acquisition across the country, as the ISI, which is global and not a national one, is not a national one. The ISI, which is global and not a national one, is not a national one. The ISI, which is global and not a national one, is not a national one.

The ISI, which is global and not a national one, is not a national one. The ISI, which is global and not a national one, is not a national one. The ISI, which is global and not a national one, is not a national one. The ISI, which is global and not a national one, is not a national one.

The ISI, which is global and not a national one, is not a national one. The ISI, which is global and not a national one, is not a national one. The ISI, which is global and not a national one, is not a national one. The ISI, which is global and not a national one, is not a national one.

The ISI, which is global and not a national one, is not a national one. The ISI, which is global and not a national one, is not a national one. The ISI, which is global and not a national one, is not a national one. The ISI, which is global and not a national one, is not a national one.

## Margaretha Kublow, Global Financial Resilience Leader, World Wildlife Fund

It is necessary to incorporate biodiversity information into climate analysis. The current lack of climate resilience, the fact that nature has the cost of inaction a great deal greater than the cost of proactive action.

If we only look at climate in isolation, we are underestimating the economic/financial risks of climate change and the economic/financial value of biodiversity loss. It is an economic good practice to measure climate and biodiversity separately for financial regulation or any financial institution that analyses risk; in addition, they must ensure that it is their risk and financial rather than one up to the risk taker.

The Network of Financial Institutions Supervisors for Tackling the Financial Impact (NFI) along with others<sup>1</sup> have been examining the relationship between biodiversity loss, financial risk, and financial stability<sup>2</sup>. This document shows evidence that biodiversity loss could have significant economic and financial implications as a result of physical risks to those who rely on ecosystem services, in addition to the transition risks posed by changing policies designed to avert biodiversity loss. Physical risks are those difficult to quantify and become a multi-quarter challenge because it may be that they simply increase the price or do not occur there, and the benefits are public good.

Putting a value on the biodiversity in place with a low number is the first step, but specific measures are also needed to fix or standardise the numbers.

## Katherine, Senior Program Development Manager, Identification

The financial sector uses a wide range of policies and general tools to guide investment decisions, including climate risk. When it comes to climate-related risk, there are several different datasets and tools that can be used. But there isn't a single tool to integrate nature into this investment and engagement.

While there are pros and challenges, there is a diversity of ways that can already be taken. The first one that we think about is looking at the priority sectors for nature, whether with a high impact or dependence on nature. What are some of those impact material factors we already know on the use of land, water, forests, and pollinators among others.

When looking at areas of biodiversity loss, some of the data may be in the TCFD reports. The issue of dependency it is more difficult to quantify, but there are recent analyses, i.e., by the World Economic Forum and the World Bank. The geographical location is also important for a spatially explicit assessment of biodiversity risk.

One can start extracting climate-related data and thinking about it from a biodiversity perspective. It is this also important to aggregate both together, which is what these matrix, tools, and datasets.

We have a study on the horizon<sup>10</sup> to measure actions to address biodiversity loss. A better results are very similar to those observed by the previous generation, as are the technical barriers to data and metrics.

There is also a general lack of awareness about what biodiversity loss means for the financial sector and how it is connected to climate change and other issues such as human rights, inequality, financial regulatory requirements, investors, lenders, and private financial institutions must develop new views around this.

## **Accumulating Significant, ISSI-Specialized, Standard & Poors.**

As an investment and/or corporate risk, climate change has taken the form and reflects in the number of companies that are setting an strategies and various climate strategies. Companies that become more sophisticated in the way they collect data and how they manage their complex issues, this helps drive the sustainability agenda. Sustainability change is continuously on our minds, even about. Hence there is a lot of moving, many elements are quite independent.

We also worry on climate action theory, data and the performance of companies. Companies dependent on nature depletion, threatened with climate change and biodiversity loss, have shown a decline in the performance of their this year over the previous years.

We also need to improve climate risk indicators, for example, geographic exposure indicators to understand the regional or local particular events, problems and/or to highly regionalized activities in industrialized locations.

Physical risks continue to be one of the biggest challenges, at least in terms of measuring the true financial impact of asset impairments and the potential for increased operating costs and the possibility of revenue loss. And there is much we can learn and apply to the current biodiversity challenges.

### **Current international trends in sustainability-related information disclosure**

Since 2019, efforts regarding to develop a comprehensive reporting system that integrates sustainability reporting with mainstream financial disclosures. In September 2020, the principal framework and standard setters – namely IFRS, Global Reporting Initiative (GRI), Global Standards Board (GSB), Global Reporting Initiative (GRI), International Integrated Reporting Council (IIRC), and Sustainability Accounting Standards Board (SASB) – for the first time issued a shared statement of intent to work together<sup>11</sup>.

<sup>11</sup> Statement of intent to work together to create a comprehensive reporting system that integrates sustainability reporting with mainstream financial disclosures, issued jointly by Sustainability Accounting Standards Board (SASB), Global Reporting Initiative (GRI), International Integrated Reporting Council (IIRC), and Sustainability Accounting Standards Board (SASB).

<https://www.integratedreporting.org/news-and-events/press-releases/development-of-intent-to-work-together-to-create-a-comprehensive-reporting-system>

In December 2016, during UNFCCC, the UNFCCC secretariat announced the creation of the International Sustainability Standards Board (ISSB), specifically to develop a comprehensive global baseline of high-quality sustainability disclosure standards to meet investors' information needs. In this regard, the ISSB Foundation created a "Technical Foundation Working Group"<sup>10</sup> (TFWG) which included the IASB, the IFRS Board on Climate-related Financial Disclosures (IFRSB), the International Accounting Standards Board (IASB), the Global Reporting Foundation (subsidiary of IASB and IFRS), and the Global Sustainable Council (GSC), to provide a working start for the new board<sup>11</sup>.

## 1. Assessing impact and its integration in the financial decision process

December 2, 2018

### Opening remarks from Manuel Ramos Pardo, General Director of EMMA

This conference represents an effort to improve our understanding of the environmental challenges for the financial system and to integrate them into the agenda of central banks, authorities, universities, research groups, etc. There are no readily available mechanisms of financing and of the economic and social systems.

The events about the recent COP23 in Bonn have once again highlighted the difficulties of reaching global consensus to set action objectives and step the increase in temperatures. This conference seeks to contribute to making the consequences of environmental degradation and biodiversity loss more visible and to be a platform for knowledge. Our objective is to raise awareness and encourage the implementation of a strategy agenda that incorporates the environmental aspects into global financial sector strategies. A factor considered by the financial sector to mitigate climate change is biodiversity loss, which is clearly considered, setting the groundwork for more ambitious and urgent agreements to set a sustainable built agenda.

Moving to see how various ecological services feed into the category of ecosystem, non-material, and non-market goods, is the natural link to market failures. In addition, there is a lack of measurement and valuation of these services.

Financial systems are affected by biodiversity loss, mainly through channels that have been linked to the so-called physical environmental risks. Physical risks capture the potential reduction in the quantity and quality of ecological services and can affect the ability of companies to access credit and pay their debt. Transition risks reflect the risk of changes in policy, preferences or technology due to adaptation to sustainable practices to prevent biodiversity losses.

Increasing public scrutiny of corporate investments is an example of this type of risk. The transition to a greener economy means that certain economic activities may face higher costs and certain changes in assumptions that affect the way companies. Transition risks have increased the attention that their importance is likely to increase as action is taken against environmental degradation. The demand for legitimacy there is one of the driving forces.

Financial firms can have an impact on biodiversity through their investment and lending decisions, as well as risk taking. Central banks have explicit goals to incorporate these changing challenges into policy action.

policy instruments can be adjusted to ensure rules related to the environment and monetary policy can be adjusted to avoid amplifying the effects of environmental damage through monetary mechanisms.

What can we do to help avert the environmental damage disaster? If our goal is to provide appropriate policy pathways to limit the loss of diversity and build a path towards environmental restoration, there are a host of measures under important consideration.

One first question deals about the utility function of environmental climate policy: what is how much current consumption we must sacrifice to avoid the cost of environmental degradation?

The second challenge relates to designing an appropriate policy approach. In the case of climate change, a single policy instrument such as a carbon tax may not be sufficient and should probably be complemented by other market-based policies and instruments. Uncertainty here is about the comparative utility of the taxes and their interaction, as policy making becomes even more difficult.

Some of the points where economic incentives are in the regulatory rights involve mainly the traditional market economy by explicitly including natural capital as an input in the production process and restructuring the way in which economic performance is measured and assessed, as well as setting appropriate prices for risk.

Another expert on the design of policies that have the right incentives for countries in general, and governments in particular, to implement them. This is a framework test, as the policy needed to address global warming and environmental degradation requires an unprecedented level of international collaboration. It is suggested that in identifying non-cooperative strategies it is time to think deeply about what the best feasible global governance would be to lead to a scenario that maximizes the likelihood of avoiding disaster.

## **Keynote speaker: Partha Dasgupta, The University of Cambridge**

What first question does this lead us to the state where we realize that we are really digging a hole by destroying the biosphere?

One of the reasons, and there this is the key, when at the end of World War II the attention was given to the conservation of productive capital (roads, buildings, ports, health, human capital) and so on. In that sense at the time, at least globally, since the human economy was small relative to the biosphere, we could conserve nature, which, generally speaking, was an obvious mistake that has corrected itself in a sense because in the last 50 years, since 1950, the average person today enjoys a much higher income with less likely to be in absolute poverty, a income significantly larger than 50 years ago.

Nature has been ignored in all the calculations with which development is measured. GDP is a thing, not a state: the human nature is the basis of our production and part of the foundation of the human economy, but the being-ignored is *state* (such as GDP) implies that we cannot suppose that a thing *just* has been ignored at the expense of the future. GDP does not account for the degradation of capital assets, i.e., of course, of human nature.

Take a brief's notion of the wealth of nations, what should be remembered as an initial notion of wealth, considered not only produced capital and human capital, but also natural capital. According to a study applying changes with time in 1982, during the period from 1960 to 1980, produced capital per capita globally declined, human capital increased by 14% or 15%, but natural capital decreased by 10%. In other words, we have destroyed natural capital to produce human capital.

We have already explained why this imbalance may have occurred without us realizing it; however, many of the services affecting whether nature do not have capital. When work is done, it is to use this to prevent it from at the most structure of our global economy, a system that is understood that when we talk about development economics, it really means an asset management problem.

The first point must relate about has to do with the fact that it is reasonable that the most productive regions in the world are in the tropics. This is in an extent that the world's poorest countries are in the tropics. This feature is an interesting about are most pronounced in the case of abundant services and in the case of supply chains between poor and rich countries. For example, poorer countries are supplying primary products such as coffee beans to richer countries and then transforming them into ground coffee, which is bought in supermarkets in rich countries such as the United Kingdom or the United States. There is a big supply chain, however, the price at which the primary product is sold is almost by definition lower than the conversion. This happens because the conversion of the supplier country with use of export services with it a transfer of wealth from the exporting country to the importing country. We are seeing a loss of wealth by poor countries in the supply chain, and this is the logic of closing the books. But we are creating the virtual of export trade, free trade, and globalization. I am not against globalization, but we have to think the logic of economic theory, it is strongly suggested that we need to do something about it, and something is for poor countries to create and impose an export tax to protect natural capital, and thereby protect their own wealth.

The second point is that our ecological footprint, our demand of nature's resources exceed the supply. I call this gap between demand and supply the impact of inequality. This inequality gap is currently increasing twice.

The ecological footprint is a function of income with an increasing function. It increases at a decreasing rate, which means that if you take two people, one who is rich and one who is poor, and you take a take that between rich people and poor the poor people, the ecological footprint will increase. There is a way of saying that, in order for the ecological footprint not to increase, the average income has to decrease. This is an extremely important observation.

the two enormous implications for public policy, especially global public policy, there is an absence on the part of international institutions to handle the problems that the global economy has to do with respect to infrastructure. There are two good global public goods: the open internet and the common maritime area. Both of them are extremely important. Right now, the internet and shipping areas require frequent attention. The internet itself, the internet, is supplying all of humanity with a wealth of goods and services. The shipping for the maritime traffic that generates millions of dollars transporting goods throughout the Pacific, Atlantic and Indian Oceans, the oceans are being exploited for the rest of course, they are also a shipping ground for polluters.

On the other hand we have problems in the oceans, Africa, Antarctic, etc., which are also a public good, but within national jurisdictions. The demand for freedom to protect that resource is less than the demand for security. Because even though it is a small part of the world economy, fisheries, that is not significantly, say that it produces something and not protect the resource, the real question is whether sustainable the argument is not but they often really produce something, the carrying capacity, but we need an economic response.

The recent international institutions that exist because of the changes of the global economy, which a rough estimate suggests, generates millions of dollars that could be used for many worthwhile projects. Almost all, it must be used to pay for the shipping services that the countries provide. If you take the environmental services is not a strange idea is countries such as Costa Rica and the United Kingdom, where various projects are being implemented that benefit both the forest and the fisheries, and they are paid for the services they provide in many cases, payment for ecosystem services could be beneficial. The worst kind about fisheries, the African Spine concept. It is easy to correct the idea rather than are raising but reinforcing with nature. On the other hand there are lot of regulations created, but that is part of life, the fact is that we need to think along those lines and look for institutions at the international level.

There are local communities that have already found institutional arrangements, there is an enormous amount of literature written by without design that these show that in Africa, Latin America and Asia, local rural communities have found ways to manage their land resources. Unfortunately, these communities have been undermined by international, the misunderstanding by economists and policy makers has generated enormous losses among the poorest in their countries.

Moreover, we have found that the more sophisticated economies have shifted the focus of very poor people, and at the same time, have not effective way out of the global problems we are facing. Therefore, I want to end by reminding you that the fact is not only economic, ecological or political, it is human, it is moral, which tries to solve the problems of nature. We have discussed that these communities are aware of the need in this conference, recognize that it is not a very easy subject to introduce and let others to introduce into economics in an explicit way, there are still to be on the way to solving problems.

## Panel 2: Modelling approaches to biodiversity finance

### Panel 2: Modelling approaches to biodiversity finance

What are the challenges in the definition of metrics, relative biodiversity and their impact on financial outcomes?

Moderator: Dr. David, Director of Sustainable Finance, Environmental Foundation  
Panel participants:

- John Hales, Professor of Institute of Corporate Sustainability, Royal Holloway
- Lisa Hogg, Executive Director, Business for Nature
- Thomas Hume, Managing Director Climate/Corporate Investment & Governance, IOPG
- James McIlroy, Director Policy and Strategy
- David van den Brink, Global Manager, the World Biodiversity Finance Initiative – WBFI
- John Young, Research Director, Sustainable Finance, Knowledge Institute for Sustainable Leadership

### Panel 2: Modelling approaches to biodiversity finance

This panel discussed the challenges of incorporating biodiversity risk into financial decision processes. Better knowledge were the following:

- In contrast to climate change where metrics such as carbon dioxide emissions are already tracked, the complexity of biodiversity risk requires a wider panel of metrics and interventions for better assessment for business, preventing deforestation and the preservation of endangered animal species have different direct and indirect on corporate activities.
- Metrics are hindered by practicality and cost effectiveness criteria which matter when incorporating policy frameworks, however, gathering accurate data is vital.

## Nina George, Director of Research for Sustainable Finance, Cambridge Institute for Sustainable Leadership

In contrast to business, when talking about biodiversity there is a much broader set of interests and needs, both for the complexity to understand this, you have the distinction between financial risk, physical risks, and liability risks.

“The role a type of risk looks at how it manifests itself and how it is affected by is different in a particular service, or quality or habitat quality. For example, the main question is how does this impact companies, including businesses themselves, disruption of activities, the value chain, or assets, as well as potentially price sensitivity that comes over to financial risks such as credit, market, liquidity, and business.”

On the role of business risks, it is slightly different when they manifest as a corporate business risk and come in the form of policy integration.

Initially there is biodiversity loss and best steps have begun to be used and how nature is used as a broader concept. What is important in terms of nature and nature is that they are expressed in commercial financial language and thought as more as positive to financial institutions.

In terms of the third together we have to help move biodiversity loss, what I say is that we have completely reconfigured our economic and financial systems, there are strong calls now, that already institutions and asset owners for example, in terms of achieving about 100 billion give towards biodiversity conservation annually, and that takes give towards nature that are harmful to nature (i.e., four times as much money).

The task is there, the tools are there, in addition to the UNFCCC a regulatory framework is also being built, and there are people (banks, investors, financial regulators, central banks) who are working on it, such as the Nature, the institutions where, just that we need to introduce a different regulatory.

We also need to change the conversation to talk about this as a fundamental dependency of our life on nature, and that will help us really address the financing points. The sectors that rely heavily on nature are forestry, agriculture, fisheries, food beverages, utilities, construction, and electricity. Financial institutions have portfolios that are full of those sectors. The there is a massive opportunity with climate to completely rebuild the system. We're going to bring nature into the conversation and we're going to move nature positive rather than thinking about climate and nature that goes from now. If you're doing customer engagement on climate, do a customer engagement on nature at the same time. If you're doing your risk analysis, think about environmental risks, don't just think about climate risks.

## John Tsalikis, *Andreasen Corporate Sustainability Practice*, *Cornell University*

Measuring or benchmarking is fundamentally different than measuring in science when it comes to measuring this together or positive impacts associated with investments. That's because global science has a key advantage: one metric, equivalent to some sort of unit, and those metrics provide a common language for scientists, engineers, and policy makers alike. For the past five years at least, we have had largely a morass of one thing, but when it comes to benchmarking it's very different thing.

This project or investment may seek to prevent deforestation, the user may seek to save an endangered species, and the third may seek to maintain the integrity of a watershed. Metrics can be developed to measure the success of these individual investments, but there is no way to compare which of these three projects offers the greatest non-financial returns. In other words, there is no equivalent to sort of unit equivalent to for the U.P.S. case. This is the challenge point for measuring success in benchmarking investments: there is an enormous amount of effort devoted to making sense of non-financial returns and benchmarking is primarily measure of gaps so that the extent possible, and clearly in strategy metrics to help investors evaluate some of these non-financial returns.

What's interesting to ask is, what are the common characteristics of good benchmarking metrics? Some of the characteristics are that they are standardized and can be applied across systems or across transactions. If you compare two financial returns on two very different things, such as deforestation on the one hand and endangered species on the other, that constitutes a very distinct and potentially impossible goal. The result is developing metrics that, at least in the relatively short term, allow deforestation projects to be comparable to each other while endangered species projects continue to measured or evaluated against each other in terms of non-financial returns. Ideally, these metrics will have to be applied, but they don't have to be understood and apply broadly and consistently may be able to develop very sophisticated metrics, but unless those metrics are practical and cost-effective, they will never be used. The goal these metrics to be applied by governments, firms on the ground and also of by companies and investors.

Some of the things that we value and that we have no doubt that we value, are very difficult to value in something that is quantifiable or at least in something that is quantifiable in a way that allows comparison with another value, at least for the moment. That's, on the issue of metrics, the idea that we should put a number on everything there is value in something that perhaps we have to maintain a self-censorship that there are important values that are inherent in biodiversity and which may be very difficult to quantify, but which should not present as that strategy forward.

## **Ernst van den Heuvel, Global Manager, Biodiversity Finance Initiative, UNDP-BIOFIN**

One of the challenges we face is that as a general rule, a lot of activities drive most of the practices in bringing together stakeholders with the financial sector. This is the kind of work we are doing at BIOFIN, where we help these two groups come together and sharing national biodiversity finance plans, but it is not those that put a plan, the national policies rather we help create an important backbone.

Indeed, there are now a number of important tools available to BIOFIN, as the a series of private sector spending advice to the sector of banking on the issue of corporate and a wide range from which finally they are spending on biodiversity 0.5% of the corporate in nature is considered a success.

One limitation that we see in the early stage despite this important global instrument, the finance is not only to look at the results, but also at indirect risk and impacts on nature. There is increasing evidence that the real impact and return on investment is not there. This not only reduce the negative impacts of investment for example, a climate, we may find that your energy investments are at a position for nature, but if we look closely we know that a wildlife has various impacts on birds and bats, another hydro-power has effects on fish.

Biodiversity is a hot and complex issue, a new tool to approach it in a systemic way bringing together the most important actors in the natural sector and the local community and let them work together on the local national platform we can suggest.

We also need to look at the current state of biodiversity, that is what BIOFIN is doing as it is also important that we see where the follow up of policy process. Within a country, the government needs to establish conservation policies as the first line of defence, a defence should come from the top of the hierarchy, then, in the second step, you have already secured the most important parts of the natural areas, and after that we could see where we could possibly have some biodiversity loss that is acceptable or not. And here is an important financing piece. There is another piece regarding scientific research investments, which is the third avenue for national policies and through the voluntary, but most countries have developed various financial policies that resulted in nature.

## Box 3.3: sensitive thinking: Business for Nature

Modeling (like any other assessment tool) is key before commitments are made with respect to nature and biodiversity as it is necessary to be sure those impacts and dependencies are understood (although thought to be completed) (synthesizing has been attempted for decades and there are now several tools available for example, threats can be used to display which sector, what, geography, what the major impacts and dependencies are going to be, and therefore the associated risks and opportunities).

As terms of assessment and modeling, there are four characteristics to consider:

a) Where is what what going after: where those impacts and dependencies are taking place? It is necessary to know on the land and also where most of the value of the investment is at risk.

b) What is the nature of biodiversity in the company and in the portfolio of business/investments?

c) What are the other natural systems/properties/measurements that matter and, where, what matters health systems? No, what is the status and where are those impacts and dependencies occurring? This can talking about nature, which means understanding the complexity of natural processes. People may think, “the most quarterly counts,” but the natural world does not work in quarterly cycles. This also need to know whether the impacts are going to be positive, or have deleterious, or temporary, such as pollution.

d) What is affected by the impacts of the company with its dependencies? The need to do with the dependence of indigenous people and local communities and the benefit of their profound knowledge and experience.

As how to consider the multiple impacts on nature in terms of risk, it should be noted that economic valuation can be very useful. The key, in an integrated way and using appropriate tools, that a way to try to balance and incorporate the multiple and different impacts and dependencies. Starting on the real impact and value for people and business. There are examples such as the case that the Natural Communities that have signed the “Business for Biodiversity Pledge”<sup>11</sup>, which consider that no collaborative, sustainable means that biodiversity impacts as well as to set targets and report on biodiversity impacts by 2020. The result is ensure that we can take it as an appropriate, credible, robust and data-based way. This also need governments to implement ambitious policies so that policy actually gives companies the courage to start quickly measure and change their business models.

Along nature and the characteristics in above, the result is that nature equivalent to a fit case. The need to communicate in that framework and recognize nature and ecosystem many. Finally we need to eliminate or reduce harmful activities and industries that are not helping to achieve a nature-positive world.

<sup>11</sup> <https://www.biodiversitypledge.org/>, September 2019. Business for Biodiversity Pledge: Business for Biodiversity Pledge. <https://www.biodiversitypledge.org/>

## Circle K: Managing Director Global Responsible Investment & Governance, IFC

As others are very happy to mention and our transparency and disclosure, ICF has established a responsible investment policy through three transitions: the first is the climate and strategy transition, the second is the digital transition and the third is the natural resource transition. As natural resources and biodiversity are one of the forces through which we look at investment policy and our investments.

The two perspectives we adopt are risk and opportunity for climate change, so there is not really a top-down and bottom-up approach. For top-down, we have three or four levels of climate risk exposure against different indicators for the entire portfolio, and for bottom-up, the portfolio managers have to explain for their specific investments, what the climate risk exposure might look like and how it could be mitigated.

Regarding biodiversity, we now look at both opportunities and solutions in which we can start to integrate into the country, you look into examples of climate change, infrastructure is important, transition risk, and new technology risk. For physical risk we look for very asset-specific data sources, for example, for our real estate investments, we have historical investment information called the surface that that data shows. How could you use it for biodiversity? It's not a story, but I emphasize the importance of having tools that allow you to benchmark assets against an objective and is ongoing. There is one question we are always asked: what can you do about it? There are very broad spectrum of how we and how very important to think about how to structure an investment opportunity so that the different players in the investment chain can contribute capital.

## James Salmons, ClimateRisk Leader, Ratings

First, there is a separate, growing, but the political impetus to make the transition fully come into with climate change. The issue becomes something that matters to the sustainability manager, and now it is something that matters to the chief risk manager. With respect to the measurement, you have to consider proximity and ability to mitigate all the company level between the sources and levels of climate change and between high- and low-impact companies. You have to be specific and use company-level examples in terms of robust probabilities and severity.

The second point is that the model needs to be specific. They need another layer of information to take into account the policies that companies put in place to improve their sustainability profile, so that policies and measures can continue to stand in those companies that they have successfully influenced in the transition of their businesses.

Third, measurement is a key issue. If the major financial services companies withdrew investment from certain high-impact companies, then other parts of the financial services sector that are less regulated or have less shareholder pressure will step in and provide the funding. Therefore, there needs to be a system to take account of funding also based on what companies are planning to do, meaning whether the the financial services provider follows it or not.

The fourth point is about incorporating biodiversity into the risk factors and measurement issue. It's important to get the front office teams excited about the opportunities for financing the transition. The issue is climate it's going to take about their vision of investment over the next 30 years to transition our economies to net zero (that amount of funding needed is a real-strengthened working example for opportunities exists). If you can identify where to place your bets.

So, while there may be a core of people in banks, a robust manager and investor building work, there are thousands of people on the front lines of institutions, who need to know how to identify opportunities to finance the transition, so that they can do so at issue that can be a positive driver of business growth. Finally, it should be emphasized that there needs to be legislation that forces financial and climate companies to disclose their climate-related risk.

## **Keynote speaker (British Daily, Faculty Director, Harvard National Capital Project, Harvard University)**

As we look across the challenges and see the ever increasing mark of humanity across the planet, there are several questions that we need to integrate more effectively into the financial decision-making and policy that underpins the financial system.

First, how much and where should we produce? Second, how can we ensure people a retirement for the late-life and address what can almost be termed the financial retirement? And third, how can we get beyond market surface and to measure a sustainable progress?

All of the requests relating nature to value seems not necessarily in monetary terms, but it is a deeply meaningful way, and that has been the transformation challenge with relatively recently, we looked to philosophy, spirituality, or even poetry and aesthetics, to talk about those values (and they can still remain away). We have come a long way to say the shareholders to get to where shareholders.

It is remarkable to think about where we started to operational a global approach, and how much, came at a time when every part of the world and every social sector had its own unique way of thinking about nature. We helped to enhance a global view, developing a universal language for thinking about and characterizing the diverse and different elements of nature and their interrelationship.

It brings us to the point where we are now, in the middle of the new revolution, and to think about how does value nature from only in the interrelationship and ultimate interdependence of people in the ecosystem, but rather by value globally given. And with this, coming to a shared understanding of how people, societies and institutional systems in different places, value nature, proposing a universal language and characterizing a system that can be used globally and give dignity to differences around the world. But rather we're there, allowing us to work together in a fundamentalism that takes the account into consideration.

In the context, there has been some who have played a key role in advancing the knowledge base and putting it into practice, making it accessible and meaningful to many different decision-making contexts around the world. There have also been many, sometimes and scientific efforts that stand out as pioneering.

After the Millennium Ecosystem Assessment and other global scientific efforts, the time has come to begin operational these into a universal approach.

this software was the *TechnoProject Project*<sup>10</sup>. It is a platform based on science and integrating it with economic and technical, it is an economic and technical for everyone and thanks to scientific and technological globally the basic development and a software system. With this idea, we build a part of information about the earth system on the first seven or seven get around the world, so that any place not require consultation with respect to the idea that nature play its contribution to water security, climate security, other, food, safety, security, health, both natural and physical, the ability to be resilient in the face of increasing risks and threats such as floods, fire, therefore a highly integrated system. This system has been adopted by all countries to some degree and various places, it is being fully utilized. In 2019, we have created the system, which has also started to be deployed in a number of cities in Europe, North America and Asia, among others.

The way it works is to think about a change in management policy in finance and then look consistently and with data at how that would imply changes in the company, structure and conditions. The system provides answers of all these benefits of nature for people.

Finally, the idea is to build a system of accounts, an integral approach and a total high-level system in particular that see that companies understand nature's contribution to society. There is increasing interest in this, such as the recent statement concerning Sustainable Development Goals to change the nature and process, analysis, characteristics, evaluation, advice, measurement and operation by 2030, building on the measurement progress that has been made.

## Panel 4: Capital markets and biodiversity

How can capital markets generate investment opportunities that support the goal of sustainable development? What are the emerging practices or solutions?

**Moderator:** Stefan Schlegelmüller, Senior Policy Fellow, the Stockholm Research Institute on Climate Change and the Environment, the Swedish Institute of Economics and Natural Science (SWE)

### Panel participants:

- Christopher Henderson, Head of Climate & Sustainable Finance, ICB
- Thomas Bernero, Chief responsible investment officer, ICB Switzerland
- Verónica Olvera, Director, and Andrew Watt
- Ben Henderson, Managing Director, Sustainable Finance and Capital
- Greg Wilson, Group Director, Biodiversity and Natural Capital, Climate Change and Sustainable Development, ICB
- Matthew Arnold, government, impact finance & markets, ICB

### Panel 4: Capital markets and biodiversity

The panel discussed the relevance of biodiversity for different organizations (ocusing on how they integrate their commitments) and the challenges and opportunities for biodiversity reporting, ranging from the creation and collection to the regulatory framework.

## John Henderson, Managing Director, Sustainable Finance, AIGM Capital

Now is quite an interesting place for biodiversity from a financial perspective of view, and to put it in context, it is highly dependent on climate change and environmental issues. Many of its activities are highly dependent on and ultimately connected to nature, such as agriculture or fisheries. In addition, a significant proportion of the population has direct and daily contact to the world's oceans. It is interesting to see these links.

When thinking about climate-related natural assumptions, an emerging framework for thinking about risk is a function of factors, meaning the severity and frequency of physical events, exposure, and vulnerability, meaning the susceptibility of the exposure to that event. In line with this growing recognition of the role of biodiversity and physical factors risk, and their implications for the financial system, for example, the extent of flooding is a watershed following a typhoon, in part, depends on the type and distribution of vegetation in the watershed which influences the intensity of water reaching the river systems and ultimately the damage. Another example is forest fires and the impact of forest damage where not only, mangroves, coastal wetlands, play a role in determining the extent of physical climate risk vulnerability, there are costs and consequences of disappearance of vegetation of this type.

As an example, the Monetary Authority of Singapore has developed environmental risk guidelines<sup>22</sup> differentiated from those of other jurisdictions around the world risk, they cover environmental risk beyond climate change, which is the broadest factor of many jurisdictions around the world. They explicitly cover biodiversity loss, anthropogenic climate change, they recognize that these two can interact with notable effects, separating environmental factors. The guidelines also go beyond the climate include environmental and changes.

We are also thinking a sustainable approach here, and the clean energy and mobility, manufacturing and agriculture systems within one of the key drivers for biodiversity in the climate.

One interesting element is that there are more evidence connections between biodiversity affects the carbon risk of our portfolio, risk of whether it is a more significant risk to cost and financial cost companies, we are increasingly thinking about how biodiversity loss can increase asset vulnerability, relevance or profitability impact.

All factors, even though biodiversity is a fairly local issue, local operations often require more configurations of nature. Another issue that has a great potential to gain, is to rethink industries and try to make them positive for nature. An implication, I think, a great potential is biodiversity measuring, new technologies and the use of "big data" algorithms to generate simple metrics, scores, classifications and its understanding.

<sup>22</sup> Monetary Authority of Singapore (MAS).

https://www.mas.gov.sg/media/infocentre/press-releases/2022/02/20220209-environmental-risk-guidelines  
https://www.mas.gov.sg/media/infocentre/press-releases/2022/02/20220209-environmental-risk-guidelines

## **Fabrizio Lamanna, Head of CFI Responsible Investments, Amundi Group**

Because the constraints are not 100% and are quite flexible to align portfolio with our targets, there is a little variation in the volume of divestment. The most part is given the good news that it is available. The bad news (reducing 100% because increasingly rigid, if because 100% is too good, then now there is still some a heavy restriction) doesn't make market selling pressure on the stock, and we should reduce carbon emissions by 10% by 2020. The likelihood that policy makers will put in place carbon new restrictions is very high.

On how we include biodiversity risk in our portfolio, we have companies where we evaluate physical risk; for example, together with Multilateral banks, we developed a fund that has a carbon mechanism and invests in green bonds. We also have a fund infrastructure bonds, which we try to match in companies with exposure in the food chain; in this fund, we are committed to reducing our water footprint by 20%.

On the geographic aspects, we have a very clear mapping of the focus of the geography and the activities that we need to keep along (example of the economy). The rule about pricing things is that capital markets, not work and resources results is available and that way that, when we talk about biodiversity, it is about our values, though we should not put a price on it, we should just say "we are not going to touch that". No, it's not about knowing the price of the asset and how much it contributes to the whole company, it's just about saying "that has to be protected, period".

## **Lucinda Martin, Director, Eco-Business Fund**

It will start with costs. And this is the business where there are different degrees of preparation to face this new reality. Instead of the markets where we operate, regulators are not paying attention to the costs. Firms started with environmental and social risk a couple of years ago, but what you see is that most firms still don't include them as key risks that institutions need to assess.

Many institutions have gotten ahead of the regulator, so they have decided to be pro-active when the regulator calls. This is already visible, especially in the target markets, where they have been working on the design and implementation of their environmental and social management systems.

The Eco-Business Fund has worked with about 10 institutions in the region to help them have a system not just for regulatory compliance or for markets but is integrated into the way they do their operations. These were institutions that at the end only as a risk, but also as business opportunities as they can offer value solutions in addition or to improve their core.

There are also needs and requirements. We have a double responsibility to generate impact, but also benefits to our investors, so that's where we focus gap: the generation of opportunities, for example, the more very small, the operators are very young and not experienced enough. And the more problems we have to solve, because we cannot do any project with a budget of less than 10 million, and most of the projects we run are below that threshold.

## **Christoph von Plessburg, Head of Climate & Sustainable Finance, IIF**

A current trend is transparency: public media, mass media, and social media are forcing the top management of the world's institutions to act in a better way, you can read it in the literature, institutions have to improve the sustainability, otherwise we will continue to invest in them. That means that the way we begin today forms a basis for the development of the future. With the combination of transparency and purpose, which are the two major trends, sustainability will go all the way to the top of the agenda.

Our management has to comply with the various stakeholders, not only regulators, but also markets, yourself, society, etc. When managing sustainability risk, we are here to 1) reporting the business about, and how we compare, taking the global level and doing that. There is a need to create new relationships between institutions, financial and non-financial, to make sure that the risks being managed are understood. Also, this needs to be explained to the investment communities in order to secure funding.

There are different types of risk, in the context of climate change mitigation, in the context of adaptation and in the context of biodiversity. Thanks to transparency a lot more information, there will be a evaluation of green and change-in-operations.

On the other hand, the time horizon in which markets work is too short, and most of the things we have to do for preserving are 100 to 100, to 1000 years. And unfortunately, we are in financial economy. Hopefully this is going to change. Because we need to document future values to our economic markets. We also need to create an ecosystem for planet earth, create an economic ecosystem, separating a difference in understanding who are the beneficiaries and the contributors, and the idea is clearly to separate those things with economic values.

The lack of information on projects is a major challenge and a barrier that needs to be addressed. An example of this is the large number of renewable projects that may be out there, of which the financial sector and investors are not aware.

And finally, in creating some thing, encourage transparency, because investors will provide best behavior.

### **Matthew Donald, The Global Leading Impact Finance & Markets**

Professional markets where we are conscious commitment to change. If larger markets there significant means to monitor what the amount of expertise, clearly, and challenge that all these commitments could be consistent. There is a capacity issue to move from these commitments to effective not just actions. Also, carbon tax and market, that technology that they're not and, capital markets are complex.

The finance community is working with financial institutions. While most investors want to maximize returns that is optimizing a conventional economy, and there's a lot of money, but often there's also some tension. I don't know if it's a regulatory challenge, but it's potentially an institutional challenge of how to incorporate transactions that are often in conflict with each other.

Also, on the one hand, we have an extractive and destruction economy, and on the other hand we have one that is regenerative. The extractive economy feeds collapse, but there are people and institutions that will fight to prevent. We can make the transition, but it's a fight.

We also have to realize that the projects are not only financial, but they are also projects where relationships, habits and governmental processes that're consistent.

## Greg Watson, Principal Specialist, Biodiversity and Natural Capital, Climate Change and Sustainable Development, E&S

One of the challenges is that the language used does not connect investors and scientists. Between policymakers, central banks, the Ministry of planning and the Ministry of finance, there are different types of programmes. They have an infrastructure plan, a climate recovery plan, a low-carbon recovery plan, a climate change plan, and they may have a biodiversity plan, and tying all of those together is that the points where often there are huge overlaps where a substantial number of activities provide benefits across a wide range of those.

There are different goals with different areas, but all of them have a great interest in that ecosystem, in maintaining and restoring it, and also in generating a financial return that can come and then use that ecosystem in the long term. So, we have to think very carefully about how to bring all those groups together in different types of programs – in countries where the debt burden is high, there is an interest in financing those kinds of activities, and there is a need to create new jobs.

But there are challenges in terms of budgeting and choosing priorities, and also sometimes pressure in the territory happens because there is an economic reason for it. For example, to build economic reasons that there come and sometimes the others.

In opportunities, there are several one of the things we have been working on is a project with the New York State Thruway, with a new administration the National Trust Company, National Thruway Trust, have been working to offer natural capital solutions to the public or private trust and not create a trust and not company to offer the value in the public offering, so the New York Thruway Trust is an exact thing. It is interesting to think about the low-carbon and sustainable investment as alternatives to destructive position. The E&S has worked on this with national development banks, the challenge is to find way to channel that financing.

At the E&S, we have developed an integrated economic-environmental modelling platform (E&S<sup>2</sup>), which is a qualitative model for the interaction of policy scenarios and their impact on biodiversity and economic factors, which is a qualitative model for the interaction of policy scenarios with their impact on biodiversity and economic factors.

---

\*Watson, G. & Watson, G. (2022). Review of the opportunities and challenges of building nature-positive financial markets. <https://www.eandse.com/publications/2022/04/2022-04-20-nature-positive-financial-markets-review>

## 1. Opportunities: How to scale up investment in biodiversity

November 1, 2021

### **Keynote speaker Harold Kohan, chairman, Global Investing Group for Impact Investment**

There are three forces that are happening to impact our lives and our planet.

The first is a change in values. Not 10 or 15 years ago, large numbers of young people began to refuse to buy or purchase products from businesses or companies that did not share their values. They were began to refuse to work for those companies. This began to be a minority view of the population and eventually by investors.

We have seen the flow of the investment grow. We have seen impact investing (which is investing with the same intent as that but very intentionally focusing the impact intent) grows to a trillion dollars today around the world. We see on the bond market's subjecting to thousands of sustainability-related bonds and loans. A few years ago, it was thought that "that" wave of green, a feeling thing that would just disappear but the companies in climate change, small green, the rapid shift in working within organizations of the world's governments today is to not doubt that those changes in people's values are having an effect on the flow of investment, a positive to the flow of investment in business behavior.

Those who thought the world only sustainable investment without involving humans are starting to see shareholder meetings where those hostile directors are being threatened and replaced by new directors who endorse within environmental studies. We have seen a rebellion at the small shareholder meeting, and we have seen that directors that they must reduce their carbon emissions or else risk removal of their boards. We have also seen other shareholders at those 10, hostile meetings protesting against takeovers caused by the use of proxy solicitation or changing our economic today within change in values at the root of this.

The second major force is the power of technology which has been plugged by combining artificial intelligence, augmented reality, genetics, and computing. This makes it possible to impact and make investments to see that technology that never anticipated that 10 or 15 years ago we did not have this market that today's entrepreneurs are investing in virtual world and virtual market integration while having a high return in profits. The first known example of this is Tesla, a company that through new technologies completely transformed the industry into electric vehicles.

The third force also comes from a technical technology in labor ability today through computing creating data in measure in a greater way in monetary terms, the impacts that companies have through their operations, their forms of employment within their products, or people and the planet.

If we look at the total estimated damages on which the *World Economic Outlook* is published in monetary terms, in dollars, the damage caused by 1999 public companies around the world, which have provided us with enough information to be able to report on their impacts, of these 1,999 companies, that made those damages in a year that they made in profits, 1,999 made damage equivalent to a quarter of those of their profits – but the other 1,000 made damage of less than a quarter of their profits, showing they have an even path to their bottom line. – But together those 1,999 companies generate 1,000 dollars of damage in a single year. If you look at the correlation of the data with stock-market prices, you can see that the markets are already taking the impact into consideration.

There is also an element in measuring the impact of diversity on the workplace (in terms of a company/countries). *World's Impact Management Institute* states that it is harder to calculate the impact question: that we have begun to monitor and bring them into the main financial analysis and business activities.

A very important statement was made at the COP 26, it was the announcement by the International Finance Reporting Standards Foundation (IFRS) to establish the International Sustainability Standards Board (ISSB)<sup>11</sup> to standardize impact measurement. It is significant because those who thought it would be very difficult to measure impact, and that we would never get there, are told now that if the best standards, European and American, will be measuring impact and standards across and regions will be putting in and putting in that direction, the more information and data that flows, the greater the pressure on regions to measure it. These are very good reasons to say we are going to see this.

In parallel to the ISSB, the *World Impact Initiative*<sup>12</sup> is addressing the issue of impact transparency and integrity. The objective is to create a situation where, according to the World Economic Forum, that the best part of plans for both communities and society great issues, financial firms and governments will need to start focusing on how these changes can help them achieve their highest priority goals.

These are things that are happening not because of a political system for the most part, but because of our common sense. Governments need to provide transparency to show the power of markets, companies and how to change the behavior of companies. It is hard to force companies to address these issues, although to prepare for these changes, but many others are not taking the seriously. It is time for governments to start taking about the importance of the transparency and the need for standardization and monetary valuation of impact.

<sup>11</sup> <https://www.issb.org/news/issb-standards-announcement>

<sup>12</sup> <http://www.worldimpact.org/about-us/about-the-world-impact-initiative>

<sup>13</sup> <https://www.issb.org/news/issb-standards-announcement>

<sup>14</sup> <https://www.issb.org/news/issb-standards-announcement>

<sup>15</sup> <https://www.worldimpact.org/news/issb-standards-announcement>

Transparency has a very significant impact:

- It creates a race to the top. No company wants to be seen as the dirtiest company on the street with the worst environmental practices or the most harmful products.

- It opens the door for non-entrepreneurs to realize what the negative impacts are and to start working on solutions that provide profitability and income similar to what their business is in, while avoiding the negative impacts or creating positive impacts.

- It enables governments with the ability to give companies incentives that those to do with them. A better system that charges companies according to the damage they cause because some companies are polluting or harming the environment more than others.

## Panel 3: Success cases and opportunities in financing land use, sustainable agriculture and reforestation

What are the innovative market instruments that improve a sustainable use of biodiversity?  
What opportunities/opportunities are being developed for land use and sustainable agriculture?  
What are the rights of indigenous communities in countries of biodiversity? What is the role of the financial sector in ensuring that the rights of nature and indigenous communities are respected?

Moderator: Hanna Kralovc, specialist researching environmental and local food financing and finance advisory, Swiss Re Institute

Introducing the topic: Hanna Kralovc, professor of agricultural financing, Zurich University

Panel participants

• Ursula Frei, CEO, Sustainable World

• Felix Frey, CEO and Managing partner, Multisource Fund

• Thomas Frey, co-founder, director of the Biodiversity Program, Swiss Re

• Georg Huber, director, Agriculture Finance, WBC

• Andrew Kennedy, founder & senior advisor, Global Ecology

• Hans-Peter Mosler, senior technology advisor, international climate finance, WBC

### Panel 3: Success cases and opportunities in financing land use, sustainable agriculture and reforestation

The panel was devoted to discuss experiences and *proof of concepts* for a better usage of biodiversity financing on the integration of biodiversity risk through sustainability, and the reduction of dependency on ecosystem services. Panel participants were the following:

- agricultural production has a great influence on biodiversity, while unsustainable practices have a major negative impact. Agricultural production is one of the major sources of ecosystem transformation, and its environmental costs have a disproportionate effect on the most vulnerable population.

## Andrew Mitchell, Alexander B. Leander-Johnson, Vikash Chetty

the global food system is probably responsible for 70% of the loss of biodiversity on the planet, currently we spend about 100 billion a year on nature protection (most of it is government money), while the value of activities that cause harm to nature is about 15 times of the government money spent on nature protection. So even if you doubled all the money the government spends on nature protection, we would not come close to "winning the battle" with nature loss. Additionally if you add the negative money for nature from the private sector it is many times more than the subsidies, and it hasn't even really been calculated (some say it could be as much as 10000 \$).

that's why conservation incredibly loses, that's why natural capital is destroyed as we create financial capital, those markets are huge, we've spent less than 1% of the private sector money to nature (should be 10% when talking about agriculture, forestry, depending on where it is it may be even a big part of the rest of the system and therefore it will not be of great importance the forestry departments).

this is much bigger than anything that climate change has thrown at us, and yet all the companies and many financial houses under the banner of sustainability and the environmental, social and governance efforts against discrimination all the "sustainable" work they are doing, that the "E" is actually a "W", actually it's "climate, social and governance", so we are doing only little on the most important aspect nature.

the growing understanding about impact assessment could be that our economy is going to change over the next few decades, and we are starting to see that GDP is no longer a good measure of the health of economies, because it values everything we build and nothing we protect.

this sector has really being understood particularly around 10 years ago another leader (not a UK politician) that nature should be put at the center of the climate solution, but this idea was short-lived because of the depth of misunderstanding. We have come a long way and what we are now seeing is that central banks are now raising nature concerns.

there are several interesting examples, and some of the main points are differentiation and a different role in how we create incentives for business to do the right thing and be paid down to small farmers. Education is another thing, so is the importance of having good long-term partners on the ground.

## Tammy Newmark, CEO, and Managing Partner, GoodInterpreneurs Fund

Business does not automatically flourish in villages or towns where businesses and residents that are inclusive nature-positive businesses. The question arises of who is going to finance that? By over the next 10 years, when the multibillion-dollar business is built “partially for the planet,” they put together examples to illustrate how one can achieve climate resilience, regeneration and growth and sustainable business.

There are many examples of this in the United States and in Europe where stakeholders make visible that these models work, including the incorporation of the business aspect, the private sector aspect, and the returns. There are business leaders, partners and many who are working on the ground, who are looking for and identifying opportunities and are addressing the challenges.

As to costs, some people say “Oh, these are small businesses and local areas,” but when you really look at the cumulative impacts of all these businesses you see big numbers of 10 billion dollars to tens, 100 billion dollars of additional capital that they have brought to these businesses. This are talking about 10,000 projects, if billion features that these local community managers or producers in other words, there really is a direct correlation between regeneration and sustainable business activities and working with local communities.

The use of transparent contribution mechanisms is also important.

Another example is the crisis for ethical markets (2008), which works with indigenous communities and has achieved very strong profiles. It should also be emphasized that when talking about large institutional investors or local assets, in many of these institutions and areas there are local communities and indigenous peoples. This could lead to conflict when “selling assets” or “buying land.” For this reason, GoodInterpreneurs Fund and the companies it works with encourage working with local communities so that they have voting rights in these transactions. The mission of GoodInterpreneurs Fund is to work with the local government, share benefits where the economic benefits that local communities obtain are real and tangible. It must be ensured that what is extracted or what a business really provides to the local community.

## **Farm to Fork Gender, Senior Technical Specialist, International Climate Trust Fund (ICTF)**

The international trust for agricultural development (ICTAD) focuses on transforming rural economies and livelihoods, making them more productive, inclusive, resilient, sustainable and to increase livelihoods. Their target population is very broad as it is the most population living in poverty and experiencing food insecurity, mostly the most vulnerable and marginalized people, including indigenous communities.

The way they work is closely with the countries of focus, agriculture, and environment, through investments on the ground so they have three or four years period of planning cycle, following a bottom-up approach, and in all the projects and investments they are doing in the countries they have four main thematic commitment and climate priority important part related to food security, youth, women, and gender.

So, they have different tools where they discuss their investment plans with national counterparts, governments, and furthermore to ensure "located" the important impact they focus for these investments.

For instance, there is a new tool called food security, integrated assessment and transportation tool (FASIT<sup>11</sup>). Through this tool they assess the impact of their investments on food security at policy level, at project level. It also provides various level information on how and where to focus.

In the context of the climate and food security, there are four areas about food security, about nature, indigenous people, about women and youth that is the result of years of work. This happens for an instance that also reflects the better integration of these different issues. The integration of issues is also expected to be used in international level system with the partners. These tools have been created through the lens of production, processing and consumption, as well as trade agreement negotiations.

Regarding the private sector, after 2017-18, they separate from their investment focus different opportunities and private companies, start or large. It supports more strong and consistent, but it is not only a matter of working up, there are things to consider, such as governance matters.

Another line of work that that is, planning is to establish an investment framework for private companies, as there are many linkages between adaptation, climate change and food security. There is also being done with multilateral banks and national development banks to show that investment framework and position and how have to invest their towards the future or future among other things.

---

<sup>11</sup> "Food security, integrated assessment and transportation" tool is called FASIT, they support internationally food security and transportation at the global level. <http://www.fasit.org/> <http://www.fasit.org/en> and <http://www.fasit.org/es>

the relationship between indigenous peoples' territories, biodiversity and forests is absolutely central. Indigenous communities are protecting biodiversity and the ecosystem in their territories more effectively than a protected areas institution has a key role to play with respect to citizens in biodiversity protection, and also in ensuring that the rights of indigenous peoples are respected during project design, a welcoming implementation.

Finally, it should be mentioned that systems are important for monitoring compliance and assessing. Systems could be replicated outside the ethnic frontiers, where, in addition to settlements, compliance with water safeguards is required a lot more often.

## **Finals Campus Minster, Director of The Biodiversity Program (GG Mexico)**

In Mexico, as in other countries, water pollution due to unsustainable agricultural practices and land use change is one of the main causes of land degradation. It can take up to hundreds of years to recover naturalness of soil. This unsustainable practices water and soil is contrary to economic development and health of communities in the lowland, but also the a regional and global impact.

Building these issues is, collaboration and collaboration between diverse actors from different sectors is needed. This example is the cooperation of GGG, on behalf of the Federal Ministry of Cooperation and Development in Germany, all titles one of the largest farmers and water resource donors in Mexico, namely Mexico and things, where the GGGG operates. This initiative is called "Agua Viva" and has been developed with the aim of promoting sustainable agricultural and consumption practices, as well as enhancing the interaction between water and soil.

First, the project has been in meetings to create a network for stakeholders in a region, working together with local communities, increasing water collection, and reducing soil erosion. It supports producers of the supply chain, but also farmers outside the supply chain who are affected by erosion in the region, and who are also water users, to make the transition to more sustainable farming practices. In most cases, farmers don't have access to loans, as they don't understand the credit application processes which are also very complex. Training is addressed in two ways: one is helping farmers with the paperwork and filling up with the bank for the whole application process to improve access to loans. The second way is creating a market fund for first loans, which will allow farmers access to these funds, and at the same time reduce the credit risk for them.

In this way, banks pay directly to the farmers, who are increasing in irrigation and technology change. The project also focuses on providing incentives for bank equipment to ensure the sustainability of these mechanisms. These types of mechanisms are, of course, extremely rare. Matthew has been doing similar financial activities at the national level to support farmers, but this time it's been it with a long-term with a system partner.

There is a need to monitor, evaluation of mining by doing a risk disclosure of social and environmental impacts using environmental and climate science. These are key elements from the financial sector.

Indigenous with the private sector have greater impact when companies have a long-term commercial interests in the region, and there is a holistic approach to addressing the issues.

Human rights also play a very important role in biodiversity conservation, and they support demands from the financial sector, such as non-discrimination, equal opportunities, participation, transparency, and accountability. When human rights are discussed in biodiversity conservation, also one needs to focus both on the rights of individuals like the right to a clean and safe environment, but also on the collective rights, particularly for indigenous communities, where there to be considered as matters that affect their land or territories. And in some countries, there must also be free, prior and informed consent.

It is necessary for communities to have knowledge about their rights, and to have mechanisms for dialogue and conflict resolution, so be able to ensure that their interests are represented it, so that they can articulate their views and have a dialogue with the private sector, with state institutions and among themselves.

When planning projects, one needs to be aware of the differences and time frame that some of these projects will have, so that they may require activities continuously, regularly building trust to commitment to encourage communities to have access based information and informed decisions at the local level about the risks a re opportunities.

## Keynote speaker Pawan Sukhdev, president, WWF

There is a growing recognition and awareness that biodiversity and its loss are, alongside with climate change, a huge threat to human well-being, and that these threats must be addressed together to ensure global food and stability.

This includes the WWF Strategic Framework at WWF, in which recognizes the interconnection between nature loss and climate change, cross-cutting issues related to conservation and restoration of forests and other critical ecosystems, as well as the movement to a more sustainable agricultural and food system approach.

On the search for an alternative agriculture just there are risks and costs but also opportunities. The so-called industrial green economy and recent estimates by the World Economic Forum suggest that a sustainable transition in the food, feed, land use and forests, infrastructure, construction, energy and extraction sectors would require capital investment of about 16.7 trillion dollars annually and could generate something like 3.8 trillion dollars in annual business opportunities, as well as nearly 400 million jobs by 2030. In other words, improving the livelihoods and profits, and the resilience of communities around the world is a very feasible opportunity that has better odds than not, even in nature.

When does it start to invest in nature? It means, investing in landscapes and waters, but it also means investing in food systems, which is about putting nature to work, providing improved food for all of us, as leaders believe when it comes to better food for better health for farmers.

The WWF Nature economy suggests that FoodTech is not food system technology that includes the information that takes place in order to grow the food and the food system is subject to its generation but food plus the transportation of these commodities around the world and then consuming the food waste, which is different from all of the food systems, and the greenhouse gas emissions from the food chain, the food system, collectively would be about 40 to 45% of the total greenhouse gas emissions, that's a lot more than the 10% that we keep referring to as greenhouse gas emissions from farming, but it's not just the food system, it's the whole value chain that we need to think about.

In other words, if we want to mitigate climate change, the food system is where we need to pay attention and bring efforts. If we were to achieve that through technological means and through ways to improve sustainable farms, that means we would require a significant increase in carbon emissions. So, it's actually an adaptation measure because it's allowing those who are most susceptible to climate change to really protect themselves.

---

\*\* [www.wwf.org/wwf-impact-report](https://www.wwf.org/wwf-impact-report)

Accounting is necessary to report a matter of applying more than one capital. It is also about political capital: in other words, policy changes. Policy reforms are absolutely essential and must be accompanied by financial instruments. This means, for example, that we must focus on the negative contribution of conventional agriculture and manage them better. We must focus on positive activities, which must be disclosed transparently: natural and physical and incorporating sustainability in management or the main or more than a duty is a concern that can be disclosed or designed.

And this is a truth understood by some asset managers and by most private equities and has been slowly seeping into the thinking of corporations, beyond which dissemination of negative information can occur in probably three different ways: by design, by choice, or by chance.

- Dissemination by choice: there is what happened to Eni in the Gulf of Mexico in 2010: the oil company was critical to the existence of a certain process articulated before the issue of disaster, which then, in turn, led to the decision to stop the digging and containing the formation of the company's business operations; the thing of its own and reputation. In this way, more than a decade later, Eni has not been covered by the company through sufficient and rigorous.

- Dissemination by choice: it is essentially what happened to the sugar-sweetened beverage industry in the US. About a few years ago, the chairman of the company decided to improve a sugar tax on the grounds of the costs it generated for the national healthcare and productivity.

- Dissemination by design: that means working in legal communities, working with financial regulators, working with central banks, working with accounting bodies, and managing not to lose sight of the negative impact of these decisions on performance, in other words, manage the issue to include not only environmental profits, but also shareholder impacts in other words, dissemination of performance include information, this type of dissemination by design could give markets the opportunity to respond by providing dissemination of capital.

Measuring corporate performance to include impacts on natural, human, and social capital, as well as a full-fledged non-reporting and disclosure. Because it is really a critical part of the public when we talk about changing the direction of the economy.

A way forward is emerging, and at the moment with the creation of the ISSB, the international sustainability standards board created by the International Financial Reporting Standards Foundation will be the standard way of reporting the impact of a company's operations on its stakeholders. It is essential that the world's business providers of financial accounting standards is now engaged in issuing sustainability standards for the private sector.

This will define whether there is a fundamental and necessary change in the way corporate performance is measured, and in capacity to ability to manage negative information.

the economy of the future is starting to come into view. We've seen a recent shift in how both the United States and most European nations estimate that the product markets for sustainable agriculture, forestry and fisheries, and construction, carbon credits, bioenergy, water, and other markets and services structures have a market potential of over \$100 billion. The economy of the future will also place a strong emphasis on risk management business such as together in risk, which are increasing with climate change.

The economy of the future could be about energy efficiency, about renewable energy, about resource efficiency, that economic opportunities as nature business into financial gains and losses, and other businesses are emerging from managing these risks and managing these transitions, from providing data to allowing and assessing the transition. Another piece about the assessment of the future is to look at profit opportunities. Some, of course, could find efficient use of natural resources, from energy efficiency, from resource efficiency, but also from creating losses, from creating the inputs and services that are associated with unsustainable practices, and reducing those investments.

So, what should we do?

- We really need to start building climate change and bioenergy together. It is recommended that disclosure of natural risks and impacts be encouraged. We will manage what you don't measure, and you need to have a better view of the present point in city supply chain, and the regulatory system for water. With private use on the climate risk, there will hopefully provide our climate future.
- Exposure to bioenergy. We must be honest and action should understand the systemic impact of bioenergy on the real economy.
- The development of natural-based businesses is important. These will make a positive contribution to nature, as opposed to business where efforts should be directed.
- It is not the argument that investments in natural capital are most urgently needed in emerging markets and economies. And we must look to align the mandates of international financial institutions with a global post-2015 bioenergy framework and policies provide finance through financial service institutions in these markets and economies.

With look at monetary policy as part of the model, they can support an economy that is positive for them and nature and bioenergy policy operations, such as asset purchase programs, broad-spread financial reforming operations, following a robust framework to integrate environmental risks. Natural risks have a key role to play in setting an example in changing their asset portfolio and creating the right incentives to financial market actors. And our objectives must be focused into objectives.

## Panel 6: Financing of marine and coastal resources: success cases and opportunities

What are the most important success opportunities associated with the conservation and governance of marine and coastal resources? How can we build up successful resource management as a guarantee of the sustainable financing?

Moderator: Marine Resource Survey Advisor, United Nations Secretariat

Panel participants:

- Marine Policy Director of Sustainability & Responsibility Directorate, Norway
- Sustainable Strategy Sustainable Trade, The Nature Conservancy
- High Policy, Department of Marine Sustainability, United Nations Secretariat
- Marine Policy, Chief Sustainability Officer, United Nations

### Marine financing of marine and coastal resources: success cases and opportunities

This panel was focused on the characteristics of marine and coastal resources and the sharing of experiences about conservation efforts and their sustainable ways to benefit from its ecosystem services. Some takeaways were the following:

- The exploitation of marine resources and its ownership rights creates different challenges, particularly on how to manage those resources. Despite the major role of governments in the ownership and taking of marine resources' exploitation, there are still challenges due to the inadequate prioritization and monitoring of application policies that successfully solve them.

## Karin Horvath, *Director, Sustainable Policy, NatureWest, The Nature Conservancy (TNC)*

In many cases, the issues are federal resources or spot areas resources. There's a consistent theme problem around the world of sustainable resource management, planning and protection as well as challenges in monitoring and enforcement of existing policies. The focus is on targeted activities, which have extensive impacts on biodiversity and climate, which has also led to economic loss and lost opportunities.

Looking just at the case of fisheries, we can see that the fishing sector employs more than 100,000 people, including coastal communities and inland fisheries, as well as industrial fishing on 18 large high seas industrial communities. At the same time, the global policy coordination has not in the implementation of fishing industry. 80%, also illegal and unreported fishing practices account for up to 10% of national fishing activities. So, in the fishing sector alone, there is a critical loss opportunity along with the depletion of biodiversity and ecosystem resources.

On another note, natural resources have generated in excess of billions of dollars in losses in tourism, in addition to the loss of mangroves and coral reefs, for example.

By ending biodiversity and ending natural capital, we are creating significant financial risk around this world. What studies have found that for every dollar spent on protected area management, we can achieve up to 10 in benefits. However, despite that opportunity we are more than \$100 billion per year short from managing and conserving existing protected areas that's not meeting the protected areas goal to, most recently agreed to, at the 10th meeting. If you look across around this world, we are underfunded, if challenges in many cases that financing gap is significantly higher, enlarged, this is just a small illustration of all the funding needs that we're needed to create a sustainable and healthy blue economy.

To how do we create impact investment opportunities in terrestrial way, the natural resources areas, where enterprises have not in these large degradation? We need to clarify our rights, we need valuation mechanisms, stable markets. To protect areas we need finance, which are specific business generated areas for species conservation, species conservation for that, create and mangroves. It's not just about climate, it's not just about greenhouse gases, it's about getting to the right market for biodiversity, and in the case, for coastal health. Additionally we need sustainable financing mechanisms to effectively manage protected areas while creating opportunities for a viable blue economy.

How can we facilitate sustainable blue economy market? What we really need to attract private investment for nature-based solutions, without oversteering investments and flows. Make this we need "blue value of the pillar", we really drive, we need them to be defined, and we need mechanisms that these policies are seen in a coherent way that includes stakeholder engagement in a way that manages a partnership while protecting our economy, people, biodiversity resources.

Private sector activity in the blue economy, investments and global portfolios around the world have traditionally focused on ports, shipping, transportation, fisheries, oil, gas, mining, and so on. What we need to do is to reorient investments, and sustainable means into the blue economy framework and into investments through policies and support for market developments that allow the opportunity for greater private investment. We need the public sector to create the “rules of the game” another framework to move forward.

We need clear marine spatial planning of activities economic zones and the territorial sea. This process requires broad consultation and engagement with stakeholders and a well-managed process prior to the consultation and governance areas as well as are useful for economic activity. We need to define access rights, resources management regimes and establish marine protected areas. We also need to build capacity for the transition to a more sustainable fisheries administration framework.

If we're asking communities to support a marine zone and shift to sustainable economies, for example, then there are transition payments that are necessary. There are types of incentives that are necessary to manage that transition. Fisheries do you pay for all these things? Is some of the new studies strategic debt has been a big part, whether it's through debt-for-nature swaps, strategic green bonds, strategic sustainability-linked bonds.

How do we use the assets of the private sector, our own markets and the fisheries? They are difficult, they take a long time, they cost a lot and the last ones are about as they have to be very innovative.

With respect to access issues, in the case of Belize it was very important to have good relationships with the ministers of environment, economy and finance in the government, as well as to work with scientific evidence.

The importance of credit enhancement should not be underestimated. If they could not go to market with a debt rating, they could not be able to create the monetary zone to remain in conservation. This is a major challenge.

Another issue is insurance, and specifically reef insurance. MHI has worked to deploy and stabilize insurance after a natural disaster occurs across and encompasses parts of the reef that has been damaged. There are also interesting questions about who has insurance rights – what is the right to insure a reef? Whether it is the government, the private sector or the coastal communities who has the right to insurance is under consideration.

## Marisa Gomez, chief sustainability officer, Credit Suisse

Innovation at the beginning is always small and complicated. The work that Credit Suisse has been doing, and often in partnership with other organizations like UN, and Mastercard, as a large financial services organization, is to do things at a larger scale. However, the building of any market has to start small. So, it has been given the freedom and time to build about some obstacles and let capital flow where it had not flowed before and then let it replicate.

The sustainability movement in the early stages, would you not get companies in a stage where the traditional institutional investor can come in, so not all the advantages of there is a question here which is institutional investors really believe that there are sustainable things to do, then why is it that so little is invested in? The answer is that there are no structures in place to give sustainable investors.

Regarding some experiences from the point of view of sustainability, there are the debt for nature (say) and the Nature Blue Bond, and in the case of Equilibrium there are an experimental version in areas in terms of capital markets. Either you have an instrument that was selling under a debt market with compliance issues, and with a poor credit situation. The product was overvalued because they rely heavily on markets for the country's income streams. The proposal was to restructure the debt with the provision that a portion of the proceeds from that restructuring and the annual coupon of the debt would be used and reinvested in nature conservation. This prompted discussions with the government. There was also support from the core government to provide credit support and debt restructuring. The government, as sovereign bank, as bank, as private bank, and as multilateral development institution were all aligned on a single mission. It was clear that now there is an extraordinary amount of money that requires nature conservation, which will be necessary for survival and the future humanity.

Another point is that if you don't address climate change, you can't address inequality and then there are the environmental consequences and the consequences for people's livelihoods. It is about valuing the narrative that if the markets as a multi-development bank, is necessary, then you must address climate change. If you and people not to let it become protected areas, then climate compensates them for that given agenda. You have to figure out how to calculate that loss of activity for a period of time. There are many environmental institutions where, perhaps you protect those coastal resources, but create some bank within a higher effort. The question is that between nature and the markets in the equation.

In the case of governance, the Glasgow Finance Alliance for that term (forum) is a great example. If we all come together and say there are the things that we need to see that not policy makers, the balance of equations can be different. Another way is by creating capital, for example, by funding companies that are in the business of creating technological breakthroughs.

With respect to data, it is necessary to help fund prior projects in order to be able to collect the right data and aggregate it, and give more transparency protection and at the same time, be able to have sufficient transparency in the markets.

## **Trip Of Share, Investment Director, Sustainable Growth Fund, African National Capital**

ANIC has the sustainable investment fund a \$100 million fund that invests in early-stage venture opportunities. Many of the opportunities are at a very early stage, at least the most commercially interesting ones. Knowledge Capital has worked together with this institution and established a developing investment model around with capture. Whereas a more developed financing model along these lines without capture is purely venture-backed, there are some alternative finance and ownership. If they don't have the rules of the game, it's a problem for everyone, but, in the course, it's equally true because opens some access possibilities and on the flip side. This is a kind of perfect storm of challenges.

Some positive examples are sufficient investments in marine protection areas (MPAs) are often closely with high-resolution ocean-and-marine development, so they are not yet commercial. There are also opportunities in technologies and financial instruments that are develop these things and frameworks, platforms, and being developed to collect data, but it remains a challenge in the absence of a regulatory framework. In the absence of such framework, we are having to create solutions that create a better set of options for the market.

One major source of assets in "climate economy" (fisheries, agriculture, aquaculture) that includes many nature-based solutions, and the need at some point consider the value that and how technologies a response. It is important to see where the friction points are, reflect on the key knowledge gaps within their system.

Another challenge is that people tend to make the commercial viable and how to handle that too. There's a lot of commercial energy and the commercial world follows activities, but if people don't see it, it will be very difficult to achieve.

Finally, an information problem. It's very important the issue of getting sufficient quantities around questions such as "what follows the data" what does it feeding in? There has to be input stage from a political and ethical point of view.

## **Marisa Calvert, Director of Sustainability and Responsible Investment, Banorte**

In Mexico and in Mexico as a person, we understand the reality on the ground around environmental and to discuss the impact from a company that is a company, industry, facility, Mexico are encouraged towards the nature positive.

Banorte in Mexico developed a diagnosis on how financial institutions (banks, finance, and insurance) manage climate change and climate risk in their financing decisions. We started up with very positive recommendations that set the path forward. And, there was the creation of a Sustainable Finance Institute that has different working groups in terms of finance institutions, regulatory authorities, among others. There is a lot going on in terms of a financial institutions have to change and partnerships to build the capabilities around this.

One of the main challenges facing the institutions, especially continues to be implement understanding, capacity, and the use of the data needed for construction, especially in the climate and natural space. Banorte partnered with WWF and the National Commission on Biodiversity in Mexico to have a platform to determine exactly where they are going to fund and identify the potential biodiversity risk on that location.

Another example of Banorte was the continuation of parametric insurance to reduce the risk to climate and natural resources. This is in Mexico that, which is one of the regions with the greatest biodiversity and where part of the biodiversity risk is located. The parametric insurance was built around a scenario in the forest as a product trigger or parametric and payment mechanisms on how to pay for damages, where the location and use of the property is clearly identified. The trigger was related with the support of that and the percentage of the cost insured increases or decreases depending on the area used of the business. There is a similar development being made in the state of Mexico.

## Conference closing/dialogue

- Rafael Arriola (Mexico), Environmental and Natural Resources Minister, Mexico
- Carlos Aguirre (general director, United Nations Advisory Council), Mexico
- Juan Carlos Rodríguez Cordero, president, UNEP Secretariat

## Remarks

The secretariat brings about strong feelings but being the case that why are we being the case?

- About 70% of the world's GDP depends directly or indirectly on nature.
- According to the living planet index, biodiversity has been declining at every fast rate, and worldwide we have lost about 60% of the biodiversity measured since 1970.
- We now have a very clear understanding and knowledge about the importance of nature and the contribution we are putting into it, we now need have a lot of existing action in the decision-makers in the world who truly aware or partially aware of it, however, this does not seem to be enough.
- The depletion of natural capital which significant because a lot of economic risks, which also represent a big risk for economic and environmental sustainability.

## Conditions for nature preservation

- The biodiversity convention comes from the past history we cannot ask people being to adjust policy for previous agreements, they have to realize that it is important that all projects have the participation of the communities.
- The importance of indigenous communities, where 80% of their forests are under threat, most the forest within knowing that indigenous communities also benefit from nature conservation is not unique matter of justice and an ethical proposition, but also a matter of policy effectiveness.
- Having biodiversity means having economic resilience and it includes many risks.
- The other financial responsibility, we must work on further impact climate change is a big factor.
- We need appropriate framework, policies and incentives to change the behavior of economic agents towards nature. There are many natural projects, but not nearly enough what the world needs to stop the degradation of nature.
- The incentive structure major changes in incentives to impact economic, consumption and production patterns.
- Creation of political capital for conserving and investing in nature is necessary creating awareness on the risks and opportunities associated with nature is a step in the right direction.
- Significantly, there need needs to be discuss developing markets, data, and information to make financing.

## Challenges and opportunities

- 1 It is the distribution of money, growing or developing in order to protect nature is not correct, but there is a need to move from a distributive economy to a regenerative economy, there are many examples of this: society can make these two objectives compatible.
- 2 We do continue to think of economic development and nature protection as opposites. The only way to have high economic growth and development is to address the role associated with the depletion of natural capital.
- 3 There are distributive opportunities in nature-based solutions, conservation, restoration and sustainable management practices in agriculture, forestry and blue sectors.
- 4 It is need to learn more about the opportunities of ecosystems and draw all the knowledge with current science and policy debate.
- 5 It is important to have datasets on nature and have good communication with all stakeholders about the rationale and benefits of integrating biodiversity into investment processes.
- 6 Investment and companies data is needed to have useful disclosure for investment decisions, this need more quantitative and qualitative data of ecosystems and its their relationship with climate change.
- 7 Also indicators "rules of the game", resources and their criteria.
- 8 Finally, the need to identify investment opportunities as well as investment opportunities for good investments.

## The role of the financial sector

- 1 There are limits to finance, nature negative government subsidies (biodiversity destruction without degradation) in agriculture, directly through state that public money to support for biodiversity and conservation.
- 2 The failure of natural capital and ecosystem services must be recognized. There is a need to complement GDP measures, public money, efficiency, reducing the services provided by nature.
- 3 The issue of international sustainability standards was emphasized very strongly, as the importance of internationalization by large, which was deepened means of internationalization.
- 4 Data is essential for any economic or financial analysis or decision making and financial institutions can help provide it.
- 5 There is need to urge companies to make good disclosure on climate risk and biodiversity impacts, private sector leading and as financials, moving go to positive businesses paying special attention to avoid impacts and negative externalities.
- 6 There are important financial innovations occurring with as the parameters measures of the Macroeconomic could lead to shift the nature usage. Much financial innovation and appropriate policy changes are still needed to move towards a regenerative economy.
- 7 We call for the possibility of making funds and other investment vehicles that combine sustainable risk capital with commercial aspects, with nature, with special attention to climate change, conservation, and sustainable management.
